Abstract

This appendix documents the construction of an individual-by-year panel of cooperative-apartment (*bostadsrätt*) wealth and associated transaction cash flows for the universe of Swedish residents, covering the years 1999–2017. The construction combines administrative tax filings on transfers of cooperative apartments with the National Apartment Register, the cooperative-apartment wealth-tax form, broker-reported transactions, and supporting registers on property identification, residence, and tenure conversion. Apartment wealth is measured at the individual level as the product of an end-of-year ownership share, the apartment's living area, and a price per square meter. Living area is sourced from three independent registers in a fixed priority order. Prices are derived from local repeat-sales hedonic indices estimated at the parish, municipality, and county levels. Ownership is reconstructed in two parallel tracks: a transaction-based historical track derived from cooperative-transfer filings, and a residence-based current track that captures the large majority of cooperative-apartment owners who never sell during the sample window. Transaction cash flows are reported in a separate ledger with a three-tier imputation hierarchy. The aggregate of the resulting individual panel is benchmarked against the Swedish national-accounts series for cooperative-apartment wealth.

1 Introduction and Scope

This appendix documents the construction of the cooperative-apartment (*bostadsrätt*) component of the MiNA household balance sheet. The object captures the market value of households' equity in housing cooperatives. Cooperative tenure is the dominant ownership form for Swedish urban apartments, and a significant fraction of household net wealth is concentrated in this asset class. The component feeds into the household balance sheet through the apartment wealth position $W_{i,t}^{\text{Apt}}$ and its associated transaction cash flow $S_{i,t}^{\text{Apt}}$.

The central measurement challenge is that no single Swedish administrative register supplies, for the universe of residents and at annual frequency, the three quantities required to value an individual's cooperative-apartment wealth: the apartment owned, its physical size, and its market price. The *kontrolluppgift* on transfers of cooperative apartments (*Överlåtelse av bostadsrätt*; KU55, SKV 2324) is a population-wide record of all cooperative transfers but reports neither a property identifier nor an apartment area; it is filed once per party rather than once per transaction; and its reporting rules changed in 2002 and again in 2015. The National Apartment Register (*Lägenhetsregistret*) provides physical attributes and tenure but begins only in 2012. The cooperative wealth-tax form KU56 (SKV 2342) reports a taxable apartment wealth from which the apartment area can be approximately backed out, but only for the years 2003–2007. the proprietary dataset (Mäklarstatistik) administered by the Swedish real estate broker association, covers transacted apartments only and only from 2005 onward. Finally, the population of cooperative-apartment owners includes individuals who do not transact during the sample window; these owners are absent from the cooperative-transfer register entirely and their ownership must be reconstructed from data on their registered residence at cooperative-tenure properties.

This appendix describes how these sources are combined into a coherent individual–year panel. Section 2 introduces the data sources and the resulting sample. Section 3 describes the estimation procedure, defines the auxiliary quantities and their notation. Section 4 describes the six-step procedure. Section 5 states how the intermediate quantities are combined into the final wealth variable and the cash-flow ledger, and summarises the structure of the deliverables.

2 Data Sources and Sample Construction

2.1 Overview of Data Sources

The construction draws on tax filings, property registers, residence registers, and one validation aggregate series. Cooperative transfers come from the Income Tax Registry

(*Inkomst- och Taxeringsregistret*; SCB, 2016) through the KU55 *kontrolluppgift* (*Överlåtelse av bostadsrätt*, SKV 2324) form, filed by housing cooperatives. It reports the parties, dates, prices, and ownership shares of every transfer. The KU56 *kontrolluppgift* (SKV 2342), also part of the Income Tax Registry, reports the taxable cooperative apartment wealth value (*förmögenhetsvärde bostadsrätt*) for 2003–2007 and is used both to back out apartment area and to identify owners versus renters in cooperative buildings.

Physical and tenure attributes of apartments come from the National Apartment Register (*Lägenhetsregistret*; Statistics Sweden 2017b), which records living area, number of rooms, tenure form (*upplåtelseform*), and an apartment-unit identifier from 2012 onward. Broker-reported areas and prices come from the Swedish Real Estate Broker Statistics (*Svensk Mäklarstatistik*; Svensk Mäklarstatistik 2020). Cooperative identifiers are linked across registers using the Serrano database (Per Weiderman, 2018) obtained from the Swedish House of Finance Research Data Center. Conversion dates of buildings from rental to cooperative tenure is obtained from the Hittabrf register (Hitta Mera, 2013) of housing-cooperative conversions through 2013. Geographic identifiers (parish, municipality and Rutor, which identifies location on a 250/500-meter geographical grid of the Swedish territory) come from the Geographic Database of SCB (Statistics Sweden, 2015b).

Residence histories are taken from the the household-composition panel (HID), which groups co-resident adults, and the Total Population Register (*Registret över totalbefolkningen*; SCB, 2017c), specifically the residence status and address-history file (*Flyttflödet*), which links individuals to property identifiers. Family status and intergenerational links come from from the Multi-Generation Register (*Flergenerationsregistret*; Statistics Sweden 2015a). The constructed apartment-wealth aggregate is benchmarked against the national accounts series for cooperative-apartment shares (Statistics Sweden, 2017a), used for validation only.

Table 1 summarises the role of each source in the construction.

Table 1: Source data used in the construction

Source	Provider	Years	Information contributed
KU55 (*Överlåtelse av bostadsrätt*)	Statistics Sweden (2016)	1999–2017	Cooperative-apartment transfers: parties, dates, prices, shares
KU56 (*Förmögenhetsvärde bostadsrätt*)	Statistics Sweden (2016)	2003–2007	Taxable apartment wealth (for area and owner/renter labels)
National Apartment Register (*Lägenhetsregistret*)	Statistics Sweden (2017b)	2012–2017	Living area, tenure form, apartment-unit id
Total Population Register (*RTB / Flyttflödet*)	Statistics Sweden (2017c)	1999–2017	Residence histories, household composition, dates of death
Mäklarstatistik	Svensk Mäklarstatistik (2020)	2005–2017	Broker-reported area and transaction price
Hittabrf	Hitta Mera (2013)	1999–2013	Cooperative-conversion dates
Serrano	Per Weiderman (2018)	1998–2016	Cooperative identifier linkage
Geographic Database (*Rutor*)	Statistics Sweden (2015b)	1982–2015	Parish, municipality, and grid identifiers
Multi-Generation Register	Statistics Sweden (2015a)	time-stable	Kinship links (gift / inheritance flagging)
Cooperative Apartment national accounts	Statistics Sweden (2017a)	1999–2017	Aggregate validation only

2.2 Sample Definition and Construction

The unit of observation is an individual–year pair (i, t). The target population is the universe of individuals registered as Swedish residents in any year between 1999 and 2017.

The data sources described above were linked at the individual and property level and combined to form the analysis sample. Cooperative transfers prior to 1999 are dropped because the transfer-date field on the KU55 form was not collected in earlier years. An individual–year cell enters the panel either through a cooperative transfer recorded in the transfer register or through residence registered at a property classified as cooperative-tenure in that year. Individuals who do not own a cooperative apartment in year t enter the panel with $W_{i,t}^{\text{Apt}} = 0$.

3 Key Definitions and Base Variables

The objective of the procedure is to estimate end-of-year market value of individual i's cooperative-apartment holdings,

$$W_{i,t}^{\text{Apt}} = \sum_{j \in \mathcal{J}_{i,t}^{\text{Apt}}} \omega_{i,j,t}^{\text{Apt}} \cdot a_j^{\text{Apt}} \cdot p_{g(j),t}^{\text{Apt}}, \tag{1}$$

where $\mathcal{J}_{i,t}^{\text{Apt}}$ is the set of cooperative apartments in which i holds a positive end-of-year ownership share, $\omega_{i,j,t}^{\text{Apt}} \in (0, 1]$ is that share, a_j^{Apt} is the apartment's living area in square meters, and $p_{g(j),t}^{\text{Apt}}$ is the price per square meter at the most granular geographic level $g(j)$ available for apartment j in year t. Ownership shares within an apartment satisfy $\sum_i \omega_{i,j,t}^{\text{Apt}} \leq 1$.

The price-per-square-meter factor is built from a local repeat-sales hedonic price index $I_{g,t}^{\text{Apt}}$, normalised to one hundred in the first year of the sample,

$$I_{g,1999}^{\text{Apt}} \equiv 100, \qquad p_{g,t}^{\text{Apt}} = \bar{p}_g^{\text{Apt}} \cdot \frac{I_{g,t}^{\text{Apt}}}{100}, \tag{2}$$

where g indexes geographic granularity (apartment, building, parish, municipality, county) and $\bar{p}_g^{\text{Apt}}$ is an average price level for cell g derived from observed transactions, expressed in 1999 SEK and discussed in Section 4.2.5. The unit of W^{Apt} is current-year SEK; the index I^{Apt} ensures cross-year comparability of apartment wealth.

The transaction cash flow is given by:

$$S_{i,t}^{\text{Apt}} = \sum_{k \in \mathcal{K}_{i,t}} \sigma_{i,k} \cdot P_{i,k}^{\text{Apt}} \cdot \left(1 - \delta_{i,k}\right), \tag{3}$$

where $\mathcal{K}_{i,t}$ is the set of cooperative-apartment transactions attributed to i in year t, $\sigma_{i,k} \in \{-1, +1\}$ takes the value -1 for purchases (outflows) and $+1$ for sales (inflows), $P_{i,k}^{\text{Apt}}$ is the ownership share-weighted transaction price paid or received for the ownership share transferred in transaction k, and $\delta_{i,k}$ is an indicator that the transfer is a non-monetary gift or inheritance, identified by transfer-type codes reported on the underlying

tax form. Equation (3) preserves donations as records but assigns them a zero net cash flow, since they involve no monetary consideration.

The transaction-level set $\mathcal{K}_{i,t}$ is constructed from cooperative transfers using the matching procedure of Section 4.2.1. When a verified transaction price is unavailable, $P_{i,k}^{\text{Apt}}$ is replaced by an imputed value derived from the apartment-wealth variable (equation (1)) or from the price index (equation (2)); the corresponding record is flagged as imputed in the output ledger.

4 Cooperative-Apartment Valuation Procedure

4.1 Overview of the Procedure

We construct the apartment-wealth panel and the transaction cash-flow ledger in six steps. Step 1 standardises the cooperative-transfer records and reconstructs implicit buyer–seller links. Step 2 estimates the living area of each cooperative apartment from three external registers. Step 3 classifies each property year by tenure form, identifying the cells that qualify for cooperative-apartment valuation. Step 4 reconstructs the year-end ownership panel by combining a transaction-based historical track with a residence-based current track. Step 5 fits local repeat-sales hedonic price indices and constructs the per-square-meter price hierarchy. Step 6 builds the transaction cash-flow ledger using a three-tier imputation hierarchy. The final wealth variable is then constructed by combining the outputs of Steps 2–5 according to equation (1), as described in Section 5.

4.2 Detailed Construction

4.2.1 Step 1: Standardisation and matching of cooperative transfers

The cooperative-transfer register reports multiple observations for each transaction, one for each party involved. and supplies no buyer–seller link. It was redesigned twice during the sample window, generating three reporting spells (1999–2001, 2002–2014, and 2015–2017). It provides a cooperative-internal apartment label, which is the only field that distinguishes apartments within a cooperative. We reconstruct apartment-level ownership chains by linking successive KU55 records through an iterative chain-building algorithm. The algorithm matches each outgoing transfer to the next incoming acquisition (and vice versa) in a fixed priority order: (1) acquisition through gift or inheritance, (2) acquisition through sale, (3) transfer through gift or inheritance, and (4) transfer through sale. Cross-year matches are implemented only when consistent with the KU55 form's variable availability and reporting rules. The matching procedure produces a stable apartment-chain identifier and assigns each record a reliability flag indicating whether the apartment

value and cash flow are based on a verified buyer–seller match—where both parties independently report the same transaction information—or not.

4.2.2 Step 2: Living-area estimation

The cooperative-transfer register reports neither a property identifier nor a living area. We estimate the living area a_j^{Apt} of each cooperative apartment by using three external sources, in priority order: Mäklarstatistik (Svensk Mäklarstatistik, 2020) when a broker record matches the transaction; the National Apartment Register (*Lägenhetsregistret*; Statistics Sweden 2017b) when it can be matched based on residence from 2012 onward; and a model-based prediction trained on the KU56 cooperative wealth-tax form (*Förmögenhetsvärde bostadsrätt*; SCB, 2016) for transactions in 2003–2007.

The KU56-based prediction exploits the proportionality, within a cooperative in a given year, between the apartment's taxable wealth value and its share of the cooperative's total physical area. Let $\tau_{j,t}$ denote the KU56 taxable apartment value of apartment j at the cooperative valuation date t, and let $\sum_{j' \in \mathcal{C}(j)} \tau_{j',t}$ denote the sum across the apartments of cooperative $\mathcal{C}(j)$. Define the value share $s^{\tau}_{j,t} = \tau_{j,t} / \sum_{j' \in \mathcal{C}(j)} \tau_{j',t}$. Within the cooperative-year cells in which the National Apartment Register also observes a partial set of areas, we fit

$$\frac{a_j^{\text{Apt}}}{\sum_{j' \in \mathcal{C}(j)} a_{j'}^{\text{Apt}}} = \beta_0 + \beta_1 s^{\tau}_{j,t} + \beta_2 (s^{\tau}_{j,t})^2 + \theta_{c,t} + \varepsilon_{j,t}, \tag{4}$$

with cooperative-by-year fixed effects $\theta_{c,t}$ absorbing the level of the area distribution within each cooperative-year. The fitted area share is then multiplied by the observed cooperative-level total area to recover the apartment's predicted area, trimmed to a tight band around the observed range of apartment sizes within the cooperative. When two or more candidate areas exist for a single apartment across years, we use the value that is "more" consistent over time. Predictions are ultimately used only when the implied price per square meter, computed from the recorded transfer price, lies within ±25% of the cooperative–year mean.[1]

4.2.3 Step 3: Tenure classification of properties

The reach of the cooperative-apartment universe must be determined property by property and year by year, because rental and cooperative apartments share the same building stock and many buildings were converted from rental to cooperative tenure during the sample window. We construct a property–year panel of tenure form by aggregating the National Apartment Register over 2012–2017 to obtain a unique tenure label for every property in those years; we then propagate the label backward to 1999, forward to 2017, and

[1] Conflicts between two area sources for transfers within the same calendar year are resolved with a 365-day grace period span; broker-reported areas, when present, override the other two sources.

across time gaps. We overlay conversion records from Hittabrf (Hitta Mera, 2013), which provides the dates of rental-to-cooperative conversion of buildings through 2013, revising pre-conversion years to cooperative tenure where the register based label is absent. Each property–year cell is considered eligible for cooperative-apartment valuation only when its tenure form is cooperative.

4.2.4 Step 4: Reconstruction of year-end ownership

The cooperative-transfer register reports only individuals whose apartment was at some point sold, gifted, or inherited; this implies that owners do not have a transaction record until they sell. For this reason, we reconstruct the year-end ownership panel as the union of two parallel tracks: the historical track and the current track.

The historical track works backward from each transfer record identified in Step 1. We split these records into usable and unusable rows. Usable rows have non-missing transaction dates, property identifier, apartment area, and equal buyer and seller ownership shares. Unusable rows are filled through a fixed sequence of imputations for dates, property identifier, ownership share, and area, drawing information from other records within the same apartment ownership chain as well as from the residence (Flyttflödet) and household (HID) registers. The repaired rows are then folded into an opening-balance and closing-balance panel keyed by individual, apartment, and year. We drop rows whose closing ownership share falls outside the unit interval. Finally, residual current owners—individuals who acquired an apartment before 2017 but for whom no subsequent sale is observed—are carried forward to the end of the sample window.

The historical track works backward from each transfer record. We split the cleaned transfer panel into usable rows (with non-missing dates, property identifier, area, and equal acquisition and transfer shares) and unusable rows; the unusable rows are repaired through a fixed sequence of imputations on dates, property identifier, ownership share, and area, with information borrowed from apartment specific owner-chain neighbours and from the residence and household registers. Repaired rows are then folded into an opening-balance and closing-balance panel keyed by individual, apartment, and year, dropping rows whose closing balance leaves the unit interval. Residual current owners – individuals who acquired before 2017 but whose subsequent sale is not observed – are carried through to the end of the sample window.

The current track works using residence information. We extract every (i, j, t) cell in which individual i is registered at a cooperative-tenure property in year t but does not appear in the historical track for apartment j. For each such cell, we attach a living area through the same priority hierarchy as in Step 2. We then label each individual as owner or renter using a propagation rule: any individual with a KU56 record in a cooperative–year is an owner; an individual sharing a household with a KU56 owner in that cooperative–year is also classified as an owner; all others are renters. Ownership shares for confirmed

owners are imputed by an equal-split rule across the co-resident adults, with a default of one hundred percent for sole-owner households. Gifts and inheritances are identified and dated from the KU55 transfer records and assigned to recipients via kinship links from the Multi-Generation Register (Statistics Sweden, 2015a). Rows with a zero ownership share are dropped.

4.2.5 Step 5: Per-square-meter prices via repeat-sales hedonic indices

We estimate the price-per-square-meter factor by fitting local repeat-sales hedonic indices and combining them with observed transaction prices. We restrict the estimation sample to arm's-length transactions between unrelated parties, dropping intra-family trades identified through the Multi-Generation Register, transactions occurring within 365 days of a rental-to-cooperative conversion, gifts and inheritances, missing or trivially small transaction values, and transaction pairs with a holding period below one year. We further drop transaction pairs whose deviation from a national log-price–on–holding-period regression has Cook's distance above $4/(n-1)$.

To construct the index we use a recursive method that considers coarser and coarser geographical areas. For each apartment-pair k at geographic level g (starting from parish, then municipality, and finally county), we observe a transfer price $P^{\text{Apt}}_{k,t}$ at the sale date t and an acquisition price $P^{\text{Apt}}_{k,t-h}$ at an earlier date $t-h$. We estimate the index by

$$\log P^{\text{Apt}}_{k,t} \;=\; \alpha_k + \beta_{g,t} + \varepsilon_{k,t}, \tag{5}$$

where α_k is an apartment-pair fixed effect that absorbs all time-invariant attributes of the apartment, and $\beta_{g,t}$ is the geography-by-year fixed effect of interest. We take the exponential of $\hat{\beta}_{g,t}$ and rebase to one hundred in the first available year with sufficient number of sales (typically year 1999) within the geographic area g: $I^{\text{Apt}}_{g,t} = 100 \cdot \exp(\hat{\beta}_{g,t} - \hat{\beta}_{g,1999})$. A defensive blanking rule discards an entire geography's index when any intermediate year is missing, forcing the apartment in question to fall back to the next coarser geography.

The price per square meter for apartment j in year t at the most granular available level is

$$p^{\text{Apt}}_{g(j),t} \;=\; \frac{1}{|\mathcal{N}_{g(j)}|} \sum_{j' \in \mathcal{N}_{g(j)}} \frac{P^{\text{Apt}}_{j',t'}}{a^{\text{Apt}}_{j'}} \cdot \frac{I^{\text{Apt}}_{g(j),t}}{I^{\text{Apt}}_{g(j),t'}}, \tag{6}$$

where $\mathcal{N}_{g(j)}$ is the set of transactions in cell $g(j)$ with observed area and price across the sample period, and the index ratio extrapolates each transaction to year t.[2] The construction is repeated at five granularities – apartment, building, parish, municipality, and county – and we record per-cell observation counts and coverage flags so the per-apartment selection of $g(j)$ in equation (1) can draw on the most granular cell with

[2]Idiosyncratic shocks are quantified as in Giacoletti (2021) via the log deviation between predicted and actual repeat sale prices; we drop the symmetric 2.5/97.5% tails of this distribution.

sufficient information.

4.2.6 Step 6: Transaction cash-flow ledger with three-tier imputation

We construct a per-record cash-flow ledger covering both realized transactions in the historical track and the implied initial purchases of ongoing owners in the current track. Each continuous ownership period is decomposed into individual purchases ($\sigma = -1$) and sales ($\sigma = +1$). The cash flow for each transaction is constructed using the following hierarchy: first, we use transaction price directly reported in the cooperative-transfer register; when this price is unavailable or incomplete, we impute the cash flow from the apartment-wealth variable (equation (1)) evaluated at the transaction date and scaled by the change in ownership share; when neither source is available, we impute the cash flow from the most granular per-square-meter price (equation (2)) multiplied by the apartment's living area and the ownership share transferred. Each ledger row carries a tier flag indicating the source used and a gift/inheritance indicator δ inherited from the underlying transfer-type codes. Gifts and inheritances are preserved as records but enter the net cash flow in equation (3) with zero weight.

5 Apartment Wealth

The final apartment-wealth variable is assembled from the outputs of Steps 2–5 according to equation (1). For each (i, j, t) row in the year-end ownership panel constructed in Step 4, we attach the apartment's living area a_j^{Apt} from Step 2 and the per-square-meter price $p_{g(j),t}^{\text{Apt}}$ from Step 5 at the most granular geographic level for which the price-index construction admits a non-blank value, applying the priority order apartment > building > parish > municipality > county. The product $\omega_{i,j,t}^{\text{Apt}} \cdot a_j^{\text{Apt}} \cdot p_{g(j),t}^{\text{Apt}}$ is the segment-level wealth contribution; the individual–year wealth $W_{i,t}^{\text{Apt}}$ is the sum across the individual's apartment portfolio in year t. Individual–year cells with zero wealth are dropped from the collapsed panel, with the convention that apartment wealth is then considered zero. We benchmark the resulting aggregate apartment wealth against the Swedish national-accounts series for cooperative-apartment shares (Statistics Sweden, 2017a).

The transaction cash-flow ledger from Step 6 is the second deliverable. The resulting dataset preserves the transaction date, the buy/sell sign σ, the cash-flow amount, the imputation tier, and the gift indicator δ. The collapsed file aggregates equation (3) to individual–year level. Together, the wealth panel and the cash-flow ledger constitute the two deliverables of the procedure and involve 5 datasets summarised in Table 2.

Table 2: Key output measures

Measure	Unit	Interpretation
$W_{i,t}^{\mathrm{Apt}}$, individual–year	SEK	End-of-year cooperative-apartment wealth, summed across the individual's portfolio (`fborm_new_collapsed.dta`).
Apartment-segment wealth	SEK	Per-individual, per-apartment-segment contribution to W^{Apt}, with attached identifiers, area, ownership share, and per-square-meter price at five granularities (`fborm_new.dta`).
$S_{i,t}^{\mathrm{Apt}}$, individual–year	SEK	Net annual cooperative-apartment cash flow, gifts entering with weight zero (`cash_flows_collapsed.dta`).
Per-record cash-flow ledger	SEK	Transaction-level rows with sign, amount, imputation tier, gift flag, and date (`cash_flows.dta`).
$I_{g,t}^{\mathrm{Apt}}$, geography–year	Index, 1999=100	Hierarchical repeat-sales hedonic price index at parish, municipality, and county granularities, with per-cell observation counts and coverage flags (`apartment_price_indexes.dta`).

A Glossary

Term	Definition
Bostadsrätt	Cooperative-apartment tenure form. The household owns a transferable share in a housing cooperative that conveys a right to occupy a specified apartment in a building owned by the cooperative.
Hyresrätt	Rental-apartment tenure form. The household occupies the apartment under a rental contract; the building is owned by a property owner (often a municipal or private rental company).
Bostadsrättsförening	Housing cooperative; the legal entity that owns the building and issues cooperative-apartment shares to its members.
Överlåtelse av bostadsrätt	Transfer of a cooperative-apartment share. The trigger event for a KU55 filing.
Förmögenhetsvärde bostadsrätt	Taxable cooperative-apartment wealth value reported on form KU56 during the wealth-tax era (2003–2007).
Kontrolluppgift	Annual control statement filed by a third party (employer, financial institution, housing cooperative) to the Swedish Tax Agency. The KU55 and KU56 forms are kontrolluppgifter.
Skatteverket	Swedish Tax Agency; the legal authority that prescribes the kontrolluppgift forms and receives the filings.
Lägenhetsregistret	National Apartment Register, maintained by Lantmäteriet and distributed through SCB; records living area, room count, and tenure form for Swedish apartments from 2012 onward.
Fastighetsbeteckning	Swedish real-property identifier; the cadastral identifier of the building or land parcel within which an apartment is located.

Term	Definition
Flergenerationsregistret	Multi-Generation Register; provides time-stable links between individuals and biological and adoptive parents.
Flyttflödet	Domestic migration and date-of-death panel within the Total Population Register.
Inkomstbasbelopp / prisbasbelopp	Swedish income and price base amounts; statutory reference units used in tax and pension legislation. (Not used in this construction; included for cross-submodule consistency.)
Lantmäteriet	The Swedish national mapping, cadastral, and land-registration authority.
Riksskatteverket	The historical predecessor of Skatteverket. SKV form numbers are issued by Riksskatteverket / Skatteverket.
RTB	*Registret över totalbefolkningen*; the SCB Total Population Register.
SCB	Statistics Sweden (*Statistiska centralbyrån*).
